## Descriptions of New Chalcid-Flies from Hawaii and Mexico (Hymenoptera).

BY P. H. 'TIMBERLAKE.
(Presented at the meeting of December 6, 1923.)
The types of the Hawaiian species described in this paper are deposited in the collection of the Hawaiian Entomological Society, and those of the two Mexican species of Encyrtidae are in the collections of the Hawaian Sugar Planters Experiment Station.

## Encyrtid.ae.

Acerophagus debilis n. sp. Fig. 1.
This species is most like notativentris (Giranlt) among previously deseribed species, and differs in the position and arrangement of the ocelli, in the much more clarate antennae, and by lacking a fuscons mark on the abdomen of the male.

Female. Head of the same general shape as in other North American

Fig. 1. Acerophagus debitis. A. Antema of female. B and C'. Mandible in dorsal and frontal riews.
species of the genus, but rather thicker fronto-oceipitally than in most species; in dorsal view fully rounded on the sides and in front; in side view thickest opposite the anterior ends of the eyes, the planes of the

[^0]frons and face meeting in slightly more than a right angle, the face somewhat shorter than the frontovertex; as seen from in front, distinctly wider than long, but not greatly so, the sides of the head rounded, the oral margin rather broad. and subtruneate. Frontovertex about twice as long as wide, the orbits parallel; ocelli in a right-angled triangle, the anterior ocellus placed at the posterior third of the frontovertex, the posterior pair about their own diameter from the occipital margin and much closer to the eye margin; cyes rather smaller than in notativentris, somewhat less than twice as long as wide, widest near the anterior end; cheeks distinetly shorter than the width of the eyes; face with a rather shallow, semi-oral serobal impression, the sides of the impression sloping; the bottom largely filled by the prominence between the autennae, which is about oue-half longer than wide and reaches mpward to the ocular line; the scrobes proper ocenpy the rather narrow space between the sides of the impression and the prominence, and conserge and unite above in a curve. Autennae (Fig. 1a), inserted as usual close to the oral margin and far apart, more strongly clavate than in other species; scape rather wide, pedicel almost as long as the funicle and considerably narrower at apex than the scape; funicle joints all transverse and increasing in width, the fifth joint about twice as long and twice as wide as the first; club broadly oval, somewhat olliquely truncate at apex and as long as the funicle and two-thirds of the pedicel combined. Mandibles (Fig. 1b and e) of the usual type, with the outer tooth far hasan, and the middle tooth considerably larger than the imner tooth.

Thorax and abdomen normal for the genus, the oripositor sheaths protruded for a distance about equal to one-fourth of the length of the abdomen, or to the length of the middle tibial spur. Wings narrow, the disk finely, densely pubescent, but the setae in the basal area distinctly coarser and sparser; speculum narrow and only slightly widening as it approaches the posterior margin which it does not quite reach; stigmal vein narrow at base and gradually enlarging towards the apex, about twice as long as the marginal and postmarginal reins combined.

Sculpture throughont rery finely alntaceons, the frontorertex not perceptibly more granular than the rest of the body; both it and the mesonotum with very minute, seattered setiferous punctures. Pubescence on the head very short and inconspicuous, the setae on the frontovertex nevertheless rather numerous and retrorse; eyes rather densely pubescent, the setae very short and erect; pubeseence of mesonotum moderately thick and rather dark coloren, quite uniform in distribution on the scutmm, axillae, and seutelhum.

Color of head, thorax, aml abdomen about capucine yellow (Ridgway). the face and underparts of the thorax slightly paler with the scape, club and legs nearly unicolorous; remainder of antemae somewhat dusky; apex of ovipositor sheaths blackish; wings lyaline, the veins very pale brownish.

Length of body ( 0.436 to) 0.221 ; length of head, 0.235 ; width of head, 0.275 ; thickness of head fronto-occipitally, 0.151 ; width of frontovertex.
0.099 ; length of antenna, 0.339 ; width of mesosentum, 0.240 ; length of fore-wing, 0.587 ; width of fore-wing, 0.226 ; length of exserted part of ovipositor, 0.073 mm .

Male. Similar to the female, but the frontovertex is proportionately wider, or not quite twice as long as wide, the anterior ocelhus placed only a little behind the center; antennae slenderer, the club solid; the abdomen smaller, strongly depressed, ovate, and about two-thirds as long as the thorax.

Coloration paler, the vertex, notum of thorax and abdomen light orange-yellow (Ridgway), the frons shading into paler yellow anteriurly; the face, underparts of thorax and the legs pale yellowish; antennae pale yellowish, but with the fifth funicle joint and base of the club fuscous and the remainder of the elub yellowish white.

Length of body ( 0.396 to) 0.533 ; length of head, 0.203 ; width of heat, 0.214 ; thickness of head fronto-oceipitally, 0.113 ; width of frontovertex, 0.085 ; length of antenna, 0.290 ; width of mesosentum, 0.203 ; length of fore-wing, 0.521 ; wilth of fore-wing, 0.212 mm .

Described from 3 females (holotype and paratypes) reared from Pseudococcus brezipes Ckll. (bromeliae of authors) on pineapple, Amatlan, Vera Cruz, Mexico, May 20, 1922; 1 male (allotype) from the same host on Tillandsia, El Potrero, Vera Cruz, July, 1922; and 1 male (paratype) reared November 1, 1922, from the same host from Cuernavaca, Morelos, Mexico, all collected by H. T. Osborn.

Type No. 11+2, Hawaiian Sugar Planters' Experiment Station.

## Synaspidia new genus.

This genus appears to be closely allied to the Blt pyrus, Acnasius, Archinus, and Zaomma group of genera. It differs from Blepyrus, Euryrhopalus and close allies in having the head non-monisciform and withont large pmetures; from Archinus it differs in having the post-marginal vein well developed and longer than the stigmal, the ovipositor not protruded, the eheeks not umusually short, ete. From Zaomma it differs in having the eyes smaller, the frontovertex only moderately narrowed, the facial impression not horseshoe-shaped, the club less strongly enlarged, the pedicel not very short, the antennae micolorous, ete. On the whole, it seems to agree most elosely with Zaomma which, unfortunately, is known to me only by deseription.* It agrees with Zaomma in having the face intlexed,

[^1]with the frons prominent, the antennae strongly elavate, the marginal rein very short, the post-marginal and stigmal veins both long. The axillae and scutellum are elosely fused in Synaspidia as in Chalcaspis and Mctaphaenodiscus, but both of those genera have the head meniseiform.

Female. Head much wider than long, thick fronto-occipitally with the face strongly inflexed and the frons prominent; in side view, appearing distinetly triangular, with the planes of the face and frontovertex about equal in length and meeting in a right angle; eyes large, very broadly oval, largely dorsal and latero-dorsal in position; frontovertex narrow or about four times as long as its narrowest part, the ocelli in an acute angle; face with a large scrobal impression which is subtriangular above; cheeks rather short or about one-lalf as long as the wilth of the eyes. Antenuae inserted rather far apart close to the oral margin; seape slender, slightly widened at the middle, and reaching a little beyond the serobal impression; pedicel of about normal length and shape, and rather longer than one-half of the funicle; flagelhm short and strongly clavate, the funiele six-jointed and rapidly inereasing in width distad, the first joint nearly twiee as wide as long, the sixth about thrice as wide as long; club broadly oval, about one-half longer again than wide, rather longer and much wider than the funicle, three-jointed with the apical joint obliquely truncate beneath. Mandibles slender in frontal riew, expanding at apex and with three acute teeth, of which the middle one is much the largest; base of mandible expanded in a plane at right angles with the apex. Palpi short, the maxillary pair four-jointed, the labial pair threejointed.

General form of body short and robust, the thorax about one-third longer again than wide, pronotum largely concealed by the head, the collar not very strongly areuate; mesoscutum nearly thrice as wide as long, its posterior margin slightly sinuate on each side of the middle; axillae but little wider than long, not especially acute at the inner angle and rather widely separated medially; they are also elosely fused to the scutellum, the separating suture being only weakly indicated; the consolidated sentellum and axillae as a whole is about as long as wide at the base, and the apex is well rounded. Abdomen at hase as wide as the thorax and somewhat shorter, subtriangular in dorsal view with the apex subtruneate; the dorsum rather deeply concave, the venter subromeriform; vibrissal plates situated near the middle of the lateral margins; ovipositor wholly enclosed by the ventrites and the sheaths not appreciably protruded.

Legs short and normal in structure; middle tarsi with the usual tapering form and considerably stouter than the hind pair. Wings small and
pulvinate, longer than wide, the apex rather broadly rounded, the sides and apex high and deelivous. The marginal vein is about three times longer than wide; the stigmal short, slender, curved upward, a little over one-half the marginal; the postmarginal shorter than the stigmal, being short and triangular.
not reaching much bevond the apex of abdomen; the disk moderately densely pubeseent, the speenlum very distinct, the hasal area with sparser. somewhat coarser but more hyaline setac, the costal cell pubescent except next to the vein; marginal fringe very short but dense; submarginal vein reaching to the middle of the costal margin, almost straight and somewhat thickened near its apex; marginal vein quadrate-pmetiform; the stigmal rather long, straight and with a slender, short spur at apex; postmarginal vein somewhat longer than the stigmal, the angle between these two veins aente; costal cell of hind wings moderately wide and extending to the hooklets.

Head and thorax with a very finely reticulate, molerately lustrons surface, the face more lustrons and with a considerably coarser reticulation; frontovertex with fine pin-punctures. Pubescence of head and body short. fine, appressed, dark-colored and inconspicuous; setae of the mesoscutum seriately arranged, those on the axillae and seutellum sparser yet rather numerous. Coloration metallie.

Male. Very similar to the female, but the antemae are only eightjointed, the funicle with five joints, and the club solid.

## Type of the genus: Symaspidia pretiosa n. sp.

Synaspidia pretiosa n. sp. Figs. 2 and 3.
Female. Head with the whole dorsal surface sloping forward and downward nearly at right angles with the longitudinal axis of the thorax; as seen in frontodorsal view, it is strongly rounded on the sides, subtruneate in front, the oceipital margin broadly roundly emarginate; as seen from in front, distinctly wider than long, strongly romnded on the sides. with the eheeks gibbously convergent towards the rather small month. Oceiput rather deeply concave, its dorsal margin very acute; exes large, hardly a third longer than wide, their outline strongly rounded exeept at the inner orbits, their posterior margin eontiguous to the oceipnt; frontovertex narrowest at the anterior ocellus, slightly widening anteriorly and more abruptly widened at the posterior ocelli; ocellar triangle moderately aeute, the distance between the posterior pair of ocelli cqual to about three-fourths of the distanee between either and the anterior ocellus; the posterior pair contiguons to the eyes and removed about one-half their own diameter from the oceipital margin. Serobal impression large and occupying nearly the whole face, but rather shallow, indefinitely bounded on the sides, but definitely limited above by the angle between frons and face; the prominence between the antennae low and weakly eonvex, oval in outline and about twice as long as wide; the serobes proper in the form of linear grooves on each side of the prominence, but uniting above and forming the bottom of the whole impression in its dorsal half. Antennae and mandibles as in figure 2 ; maxillary palpi short, thiekest at apex of the second joint, the first two joints nearly equal in length, the second about one-half longer than thiek, the third distinetly smaller than
the second, althongh hardly shorter on its outer margin, the fourth joint cylindrical and tapering in apical half, about as long as the first two joints combined; labial palpi very short, the middle joint transverse, the apical joint somewhat the longest, conical, and hardly more than twice as long as thick.

Fig. 2. Synaspidia pretiosa. A. Antenna of female. B and C. Mandible in dorsal and frontal views.

Fig. 3. Synaspidia pretiosa. Antemna of male.

Thorax moderately convex above, distinctly wider than the depth dorsoventrally; the axillae and scutellum very strongly depressed and lying in one plane, the apex of the scutellum rery brietly elevated, yet abruptly declivons at the margin, the latter very finely acutely rimmed, just inside of which is a delicate submarginal furrow. Propodeum short and rery transverse, considerably longer at the sides and there declivous, the basal margin finely carinate; on both sides of the middle this basal carina branches, the branch on each side curving backward and outrard towards but not reaching the posterior margin halfway between the foramen of the petiole and the lateral corner; just inside of the spiracles on each side
another fine carina rums straight backwarl to the edge of the declivous portion of the propoleum, where it branches, the imer braneh eoneeting with the submedlan carina, the outer lranch extending towards the posterior lateral comer of the propodemm, still another branch is given off anteriorly and runs forward to the spiracle; spiracles rather large, oral and contiguous to the hasal margin of the propodeum.

Reticulation of head and thorax very fine and delieate, but somewhat coarser and more evident on the face; frontovertex with two longitudinal rows of pin-punctures on either side of the median line, amd an orbital row of much finer punctures on each side; mesonotum with numerous seriately arranged, minute setigerons punetures similar to the orbital punctures of the head, and becoming sparser on the axillae and scutellum; prepectal phates as coarsely reticulate as the face; mesopleura with an extremely fine reticulate shagreening; propodemm except for the earinae described ahove is mostly smooth; reticulation of the abdomen rather eoarser and more evident than that of the face and with the lines mostly transverse, especially on the hasal tergite.

Eyes with an extremely short sparse pubescence, not apparent except under high magnifieation; pubescenee of head and body short, recumbent and tark-colored, antrorse on the frontovertex and retrorse as usual on the thorax, that of the axillae and seutellum becoming sparser and the apex of the sentellum with two considerably longer setae; sides of the propodeum behind the spiracles with a very fine whitish pubescence, which, howerer, is not conspicuous; pubescence along the sides and at the apex of ablomen sparse, but somewhat longer than that of the thorax.

General color moderately lustrous black; head with a rather weak bluish-green luster, the face more lustrous and greenish; mesoseutum usually somewhat bluish, but sometimes like the axillae and scutellum, which are darker and more aeneous; lateral posterior corners of the propoleum with a rather bright bluish luster; abdomen mostly like the scutellum, hut the apical tergite has a brighter and greenish luster; antennae and leg. concolorous with the body, but less lustrous, the tarsi mostly yollowish, with the last three joints of the hind pair, the last joint and the spines on the plantar surface of the middle pair fuscous, the front pair more or less dusky yellow, the spur of the middle tibiae yellow; wings hyaline, the lisk with a very faint indefinite fuscous eloud beneath the stigmal vein, the reins brownish.

Length of body ( 1.16 to) 1.32 ; length of head. 0.497 ; wilth of heat, 0.601 ; thickness of head fronto-oceipitally, 0.325 ; width of rertex at anterior ocellus, 0.085 ; length of antema, 0.662 ; width of mesosentum, 0.561 ; length of fore-wing, 1.027 ; width of fore-wing, 0.502 mm .

Nale. Very much like the female in most respects and the following differences appear to be the most important: Vertex widening a little more at and behind the posterior ocelli, somewhat protuberant and rather more dully shagreened; ocelli slightly larger and in a less acute triangle;
eyes considerably more densely and conspicuously pubescent; antennae (Fig. 3) with the flagellum proportionately shorter, the funicle only fivejointed, the club solid, but in general shape agreeing with the female; the seape with a narrow ventral exfoliation from the apex to a little more than three-fourths of the length excluding the radicle, this exfoliation in the female being much smaller and not reaching to the middle; abdomen somewhat wider than long, rounded at apex and hardly more than one-half as long as the thorax, therefore, considerably smaller, more depressed than in the female, and with the venter not at all vomeriform.

Length of body ( 0.825 to) 1.15 ; length of head, 0.441 ; width of head, 0.507 ; thickness of head fronto-occipitally, 0.261 ; width of vertex at anterior ocellus, 0.094 ; length of anteuna, 0.542 ; width of mesosentum, 0.499 ; length of fore-wing, 0.905 ; width of fore-wing, 0.457 mm .

Described from 13 females, 8 males, reared from Pseudococcus brevipes Ckll. (bromeliac of authors) collected in Mexico by Mr. Osborn, as follows: 1 female (holotype) reared August 10, 1922, from its host on Tillandsia, El Potrero, Vera Cruz: 12 females, 3 males (paratypes), reared from mealybugs on Tillandsia and other Bromeliaceous plants, El Potrero, on July 31. and during August, 1922: 2 males (allotype and paratype) with the same data, but collected in March, 1923; 3 males (paratypes) from mealybugs on a Bromeliaceous plant, Rio Seco. Vera Cruz, March 15, 1923.

Type No. 1143, Hawaiian Sugar Planters' Experiment Station. Zeteticontus perkinsi n. sp. Fig. 4.

Female. Head moderately thick fronto-occipitally with the face slightly inflexed; in dorsal view appearing semi-circular with the occipital outline broadly and roundly emarginate; in side view appearing thickest frontooccipitally at the anterior ends of the eyes, the planes of the face and frons meeting in an angle of distinctly more than 90 degrees; in frontal view appearing as wide as long and nearly circular in outline with the hroad oral margin truncate. Occiput moderately deeply concave; eyes of medium size, broadly oval, about one-third longer again than wide, posteriorly contiguons with the occipital margin, the inner orbits somewhat diverging anteriorly; frontovertex occupying about a third of the total wirlth of the head, and about one-third longer than its own width at the anterior ocellus; ocelli rather large, disposed in what is slightly more than a right-angled triangle, the posterior pair somewhat less than their own diameter from the occipital margin, and not more than one-half as far from the margin of the eyes. Cheeks in side view of head rather wider than long and distinctly shorter than the width of the eyes, the genal suture very obscure; facial impression subcircular, extending for about
one-half of its length above the ocular line, the prominence between antennae convex, about twice as long as wide and reaching somewhat above the middle of the facial impression; the serobes proper broally united above, the sloping walls of the facial impression extending far laterad of them (in planiseutcllum the facial impression is distinctly triangular, rather shallow and strictly co-extensive with the serobes proper, and the antennal prominence is about as wide as long) ; antennal sockets situated rather far apart near the oral margin, the distance between them somewhat less than the distance from either to the nearest part of the eyes, and slightly more than twice as great as the distance from either to the oral margin.

Fig. 4. Zeteticontus perkinsi. A. Antenna of female. B and C. Mandible in frontal and dorsal views.

Antenate moderately short and distinctly clavate (Fig. fa) ; seape slightly expanded beneath and widest at about one-half way between the middle and apex; pedicel equal in length to the first two funicle joints combined, wider at apex than the following joint and sliglitly narrower than the second funicle joint; first funcle joint much the smallest, about as wide as long, the following joints increasing in width and slightly in length, the next two not much wider than long, the sixth about one-half wider again than long and nearly twice as wide as the first; club oval, a little tapering to the rounded apex, somewhat longer than the three preceding joints combined, its three joints nearly equal in length, the basal one broadest; flagellum excelt the first funicle joint provided with rather mumerous but not at all crowded linear sensoria, the whole flagellum also with rery mumerons short reclinate setae, and similar, somewhat longer setae oceur also on the seape and pedicel. Nlandibles (Fig. 4b and e) and palpi as in other species of the genus; the two outer teeth of mandibles equal, both rather shorter than in planiscutcllum, and the inner tooth placed considerably closer to the apex than in that speeies, the mandible, therefore, more similar to abilis as figured by Silvestri.

Thorax nearly twice as long as wide, moderately convex and not quite
so thick dorso-ventrally as wide; pronotum strongly arcuate; mesoseutum much longer medially than at the sides and somewhat less than twice as wide as long, its posterior margin nearly transverse or only slightly produced medially; axillae over twice as wide as long and very acute medially, their inner tips slightly separated or covered by the mesoscutum; scutellum nearly as long as the scutum, the greatest width about equal to the length, the width decreasing from near the base to the rounded apex, the sides low yet abruptly declivous, the disk moderately convex; propodeum extremely short in the middle, but strongly lengthening and becoming declivous towards the sides.

Abdomen a little shorter than the thorax, triangular in outline, with the basal angles rounded and strongly depressed with the dorsum a little sunken in; vibrissal plates sitnated on the lateral margin a little before the middle; ovipositor sheaths barely protruded, the spicula (in the unique type) lies free from the sheaths and curves downward and a little forward from the point where it issues a short distance from the apex of the venter.

Legs rather short, the middle tarsi considerably stouter than the hind tarsi, but not distinctly tapering towards apex, the basal joint about equal to the spur of the middle tibiae and about equal to the following three joints combined. Wings as in abilis, as figured by Silvestri except in the following particulars: Marginal vein fully twice as long as wide, the stigmal practically equal to the marginal in length and much more expanded at apex and constricted at base than in abilis, the post-marginal about one-half as long as the marginal; the row of about seven coarse setae guarding the proximal side of the speculum extends more than three-fourths of the distance towards the opposite margin; the second row of finer setae situated just proximad extends for the same distance as the first row and parallel with it, and there is another row of setac lying beneath and parallel with the submarginal vein; the discal pubescence beyond the speculum is moderately dense and fine, and the marginal fringe is extremely short, but dense.

Head with very fine reticulations transversely arranged between the anterior corners of the eyes and just above the facial impression arranged in lines conforming to the rounded margin of the impression, and in this manner extending downward and forward ou the face towards the cheeks; the dorsal and anterior orbits of the eyes with a row of pin-punctures, which become gradually smaller and obscurer anteriorly; frontovertex prorided also with two other curved rows of pin-punctures, beginning close to the orbital row on each side near the anterior part of the frons and curring hackward to join together in a loop behind the anterior ocellus. Mesoscutum with equally fine scaly reticulations producing a somewhat rougher effect than on the head and with numerous seriately arranged minute setiferous punctures; axillae appearing smoothish, yet with an extremely fine reticulation, the scutellum smooth and highly polished; propodeum smooth except for a small longitudinally shagreened median area, and provided with a distinct median carina, the posterior margin also carinate,
pleura distinctly retieulate throughont except on the metapleura; abdomen apparently smooth throughout.

Frontovertex with mostly antrorse short setae arising from the pinpunctures, the lower face and cheeks with similar finer setae; eyes with numerous but not dense short erect setae; posterior margin of pronotum with a row of setae about like those on the seutum; the seriately arranged setac of the scutum rather coarser and longer than those on the frontovertex, the transverse row on posterior margin containing about fourteen, and the median longitudinal rows about six or seren setae; scutchum with about thirteen pairs of setae on the basal two-thirds, which strongly increase in size from the base towards the apex; the latter evidently provided with another pair of setae, which are broken off in the type. although their position is indicated by punctures; propodeum with a small tuft of fine short setae on the lateral margins; abdomen with fine setae along the sides and more numerons setae at apex.
(ieneral color aeneons black; the head, except most of the face, with a rather weak dark bluish-green luster, the pronotum and mesoscutum with a similar somewhat more greenish luster; facial impression, axillae, scutellum, and abdomen much more lustrons and with green, brassy, and dark purplish reflections; tegulae and underparts of thorax shining piceous with a metallie luster only on the pro- and metaplena. Scape dark brown. the pedieel and flagellum blackish. Legs shining piceous, with the tips of the front and midde femora somewhat paler or brownish; trochanters, apical third of front tibiae, middle tibiae except about basal third and the tarsi, except apical joint of hind pair and apex of last joint of the other pairs, brownish yellow. Wings entirely hyaline, the reins brownish yellow, with the marginal vein a little darker. Pubescence of body wholly dark colored.

Length of body, 1.36 ; length of head, 0.417; width of head, 0.443 ; thickness of head fronto-oceipitally, 0.259 ; width of vertex at anterior ocellus, 0.160 ; length of antenna, 0.742 ; width of mesoscutum, 0.429 ; length of fore-wing, 1.183 ; width of fore-wing, 0.523 mm .

Described from one female (holotype), collected in Honolulu in 1906 by Dr. Perkins. The following note by Dr. Perkins is attached to the specimen: "In horto mco. Not previously seen by me." The species has not been taken since, and there is, therefore, some doubt that it has become established in the Islands.

## Apilelinidae.

Aphelinus maidis 11. sp. Fig. 5.
Female. Head of the usual shape, wider than the thorax, as seen from above nearly three times as wide as thick fronto-oceipitally, as seen from in front much wider than long; frontovertex only a little longer than wide
and somewhat narrowing forward; ocelli in an obtuse angle, the posterior pair about their own diameter from the occipital margin and somewhat more distant from the margins of the eyes; facial impression moderately deep, with sloping sides, the bottom occupied by the triangularly shaped, barely convex prominenee, which reaches from the antennal sockets nearly to the dorsal end of the impression. Antemae (Fig. 5) inserted moderately far apart close to the oral margin; scape about four times or a little more as long as wide; pedieel about one and tro-thirds times longer than the first two funicle joints combined; the latter equal, and about onehalf wider than long; third funicle joint over twice as large as the preeeding joint, somewhat wider than long and about one-fourth as long as the elub; club narrowly oval, as long as the pedieel and funicle combined and two and one-third times longer than its own width. Mandibles with an acute outer tooth and a broad inner truncation, the ventral or outer edge provided also with a strong tooth-like spine or lobe halfway between the base and apex. Naxillary palpi two-jointed, the basal joint hardly longer than thick, the apieal joint about thrice as long; labial palpi twojointed, both joints about twice as long as thiek, the apical joint a little shorter and slenderer. Thorax and abdomen practically as in related speeies, such as mali, nigritus, ete. Wings fully developed and with seven oblique rows of coarser setae proximad of the speeulum, the basal fourth of the disk bare.

Fig. 5. Aphelinus maidis. Antenna of female.

Head rery finely, delicately shagreened with reticulations and moderately shiny, the frontovertex with numerous fine shallow setiferous pinpunctures; thorax and abdomen moderately shiny, or about as in nigritus, and rather less shiny than in mali; the thorax with extremely fine uniform reticulations, the abdomen apparently smooth. In the pubesceuce of the head and body there appears to be not much difference between this and related speeies, but the vertex has two pairs of setae, which are considerably eoarser than the other setae of the frontovertex; one of these four setae is placed behind each one of the posterior ocelli, and each of the
other pair is placed at the posterior corner of the vertex elose to the wecipital margin.

Goneral eolor hack, but the head and abdomen may be more or less fuscons hrown, the base of aldomen more or less distinetly yellowish, althongh in many cabinet specimens appearing wholly dark. Mandibles pale brown; antenate dusky yellow; legs pale yellow, the front femora on dorsal side and front tibiae except at apex slightly brownish; midde coxar at base, hind coxae, middle and hind tibiae fuscous to blackish, the apical half of the middle femora more dilutely fuseous; tarsi, espeeially beneath, more brownish-wellow than the other paler parts of the legs, and the apex of the apical joint fuseons. Wings hyaline, but faintly tinged with fuseons, especially beneath the marginal and stigmal reins; the veins yellowish.

Length of body ( 0.554 to 0.990 ), 0.903 ; length of head, 0.276 ; width of head, 0.3 -6: thickness of head fronto-occipitally, 0.191 ; width of vertex at posterior ocelli, 0.151 ; length of antema, 0.363 ; width of mesoseutum, 0.3 .55 : length of fore-wing, 0.858 ; width of fore-wing, 0.396 mm .

Male. Very similar to the female and distinguished with difficulty in case of dry specimens, lout areraging considerably smatler in size and with the wings often a little elearer.

Length of boily, 0.533 to 0.511 mm .
Described from the following material: 32 females, 22 males (holotype, allotype male, and paratypes), reared from Aphis maidis Fitch, in ITonoluln, December, 1919. to February. 1920 (Timberlake): 1 female (paratype) reared from Aphis maidis on grass, Ewa Plantation, Oahu, May 19, 1922 (Timberlake); 2 females, 1 male (paratypes), from same host on corn, Nanoa Valley, Oahu, April 10-11, 1923 (Timberlake): 2 females, 2 males (paratypes), collected on sugar-cane, Mountain Tiew, Hawaii. January 21, 1918 (Timberlake): 8 females, 6 males (paratypes), reared from Iphis sacchari Zehntner on sugarcane. Honolitu, Angust 18-25, and September 13. 1916 (Timberlake): 1 male (paratype) from the same host on sugar-cane. Ewa Plantation, Oahur, Ausust 3. 1918 (Timberlake); 1 female (paratype) collected in Honolnlu, March 21, 1917 (Timberlake); 1 male (paratype) reared from Aphis sacchari, Hawaii Mill Co., Dilo, Ilawaii, September 16. 1913 (Swezey): 1 female (paratype) collected at Waikea, Mawaii, October 2. 1913 (Swezey): 1 female (paratype) collected at Waialua, Oahu, January 8, 1923 (Swezey): I male (paratype) reared from Aphis sp. on Scirpus maritimus L., Honolulı1. January 7. 1913
(Swezey) and 2 males (paratypes) collected in Honolulu in 1906 (Dr. Perkins).

Aphelinus maidis comes closest to A. nigritus and lapisligni Howard, and is distinguished by the characters given in the following table. In Kurdumoff's table of the European species it runs to z'aripes (Förster) and to hordei Kurdumoff, but does not agree with either, as both the middle and hind tibiae are black.

Aphelinus gossypii n. sp. Fig. 6.
Femate. Head shaped exactly as in maidis as far as can be determined in more or less shriveled specimens; antennae (Fig. 6) inserted in the usual position; the scape not quite four times longer than wide, excluding the radicle joint; pedicel ahmost twice as long as the first two funicle joints combined; first funicle joint about twice as long as witle, the second distinctly longer than the first and about one-third wider than

Fig. 6. Apletinus gosnypii. Antema of female.
long, the third about as long as the first two combined, only slightly wider than long and a little less than one-thitd as long as the club; club rather broadly oval, one-half as wide as long, as long as the funicle and twothirds of the pedicel combined, and provided with about six slender linear sensoria. Mandibles nearly as in maidis; maxillary palpi also the same, the labial pair with one joint about five times as long as thick; the terminal joint of both palpi in this species and also in maidis bears a slender, long, spine-like appendage, which may be a true but much attenitated segment, but which is regarded as a seta in the preceding computation of the joints. Thorax and abdomen practically as in maidis; wings fully dereloped, the speculum limited basad by a single row of coarser setae and by about two to five additional setae in the angle between this row and the marginal vein.

Seuphture about the same as in maidis, except that the setiferous punctures of the frontovertex are less numerons and less distinct; the pubesceuce the same, but sparser on the froms.

Color of the head and body shiny black, the base of the abdomen more or less distinctly yellow, the extreme tip of the abdomen and the oripositor sheaths also yellowish. Mandibles pale brown; seape, and sometimes the pedicel, pale hrown or dilutely fuseous, the rest of antenna dusky yellow. Legs, including coxae, blackish; apex of front femora, front tibiae except for a more or less distinct infuseation on the basal half, front tarsi, middle trocluanters, apex of middle tibiac with spur and tarsi and hind tarsi except basal joint brownish yellow; hind trochanters and hind femora clear pale yellow. Wings almost hyaline, the veins yellowish.

Length of hody ( 0.598 to) 0.914 ; length of head, 0.351 ; width of head, 0.443 ; thickness of head fronto-occipitally, 0.165 ; width of vertex at posterior ocelli, $0.174^{*}$; length of antenna, 0.434 ; width of mesoscutum, 0.396 ; length of fore-wing, 0.903 ; width of fore-wing, 0.40 .5 mm .

Male. Very similar to the female, but smaller and with the antennae slenderer, the elub being hardly wider than the funiele and more pointed at apex than in the female.

Length of body ( 0.452 to), 0.747 ; length of head, 0.29 .5 ; wilth of head, 0.358 ; thickness of head fronto-oceipitally, 0.160 ; width of vertex at posterior ocelli, 0.153 ; length of antenna, 0.403 ; width of mesoscutum, 0.302 ; length of fore-wing, 0.754 ; widtl of fore-wing, 0.349 mm .

Described from 25 females, 9 males (holotype and paratypes) reared from Aphis gossypii Glover collected in Honolulu in May, 1919, and in March, 1923 ; also 1 female (paratype) associated with this Aphis on Hibiscus in Honolulı1, April 12. 1918 (Timberlake); 1 male (allotype). labelled "on bean Aphis," presumably Aphis medicaginis Koch, collected in IIonolulu, November 22, 1904 (Swezey) : and 1 male (paratype) collected at Kilatea, Hawaii, in July, 1906 (Dr. Perkins).

This species of Aphelinus is very similar to A. mali (Haldeman), but is readily (listinguished by the characters given in the following table of species.

## Aphelinus semiflavus Howard.

Three females reared February 29, 1916, from Toroptera aurantii (Fonscolombe) collected on the Manoa Cliff trail on Tantalus. Oahur, and one female reared March 30, 1918, from

[^2]Aulacorthum circumflertm (Buckton), also from Tantalus. agree very well with North American specimens from Clemson College, South Carolina and Los Angeles, California. The wings of these specimens are clearer hyaline than in the North American specimens, the scape and pedicel are paler and in the female from $A$. circumfle.rum the wings are small and narrow, but agree in this respect with all males that I have seen from the United States, and also with one female from Los Angeles. In both of these females with small wings the abdomen is considerably blackened except at the base.

## TABLE OF CERTAIN SPECIES OF APHELLNUS MOSTLY HAWATIAN AND NORTH AMERICAN

The following table has been prepared to show the relationship of the two species described in the preceding pages, and to aid in the identification of these and other species. One Anstralian species is also included.

1. Body partly black or brown, or wholly dark........................ 2

Body wholly yellow except ocelli and eyes; wings with four basal rows of setae and a fifth row widely separated from the others;

2. Speculum of fore-wing bounded basad by several rows of setae..... 5

Speculum bounded basad by one and one-halt rows of setae or hy one row and several more or less scattered setae just beneath the marginal vein.
3. Abdomen yellowish on basal segment; seaje narrower.............. 4

Abdomen wholly black or fuscous; legs brownish, the hind femora pale yellow, hind tarsi whitish, with the basal joint brown: scape short and rather wide, about one-third as wide as long, hardly longer and a little wider than the club. . . . . . . . . . . . . . niger Girault
4. Frontovertex smooth and with very minute and inconspicuous punctures; scape blackish, about four times longer than wide, but hardly narrower than the elub; pedicel about one-third longer than the third funicle joint; funicle and club clear yellow, the third funicle joint slightly longer than wide; hind tarsi not black at the base; ovipositor sheaths dusky except at apex. .mali (Haldeman)
Frontovertex with more evident pin-punctures beset with longer bristles than in muli; scape pale fuscous, about four times longer than wide, but considerably narrower than the club; pedicel nearly twice as leng as the third funicle joint; funicle dusky, the club purer yellow, the third funicle joint slightly wider than long; hind tarsi yellowish with the basal joint and apex of the
last joint dark brown or blackish; oripositor apparently shorter
amd more temons than in mali, the sheaths shorter amd wholly
yellow ........................................................................ n . sp.
5. Wings large and comparatively wide, the disk beyom the speculum finely and densely pubesent, the marginal fringe comparatively short and often inconspicuous
Wings comparatively small and narrow, the stigmal rein reaching far heyond the middle of the costal margin, the disk beyond the speculum with coarser, sparser setae, the marginal fringe, eomparatively long and conspicuous; abdomen exeept the lateral margins usually wholly yellow; the male with elongate antema, the third fumicle joint not much shorter than the long, slender club .........................................semiflatus Howard
6. Head wholly blaek 7
Face yellow, but the frontovertex brown or blackish ....................................abdominalis (Dalman) and allies
7. Front and middle legs not wholly clear yellow

Legs wholly clear yellow, except the hind coxae and tibiae; ablomen not fellow at base; seape not over three times as long as wide; wings clear, hyaline.................................................intus Howard
S. Middle and hind coxae and tibiae brown or blackish, the hind femora clear rellow, remainder of legs yellowish although the front femora and tibiae may be more or less dusky; abdonen sometimes but not usually distinctly yellowish at the base in dry speeimens; antemar much as in nigritus but the seape is about four times longer than wide; wings with a faint cloudiness on the disk mostly beyomd the speculum ....................atidis n. sp. Legs brown or blackish including the hind femora. lut the tips of the tibiae, the tarsi, and all of the front tibiae more or less distinetly yellow; antmbae about as in maidis; wings with a faint but distinet smoky eloud on the disk, deepest below the marginal win ...............................................................sisligni Howard

## Aphytis Howard.

In 1908, Dr. Howard suggested that it would be desirable to segregate the aphis-feeding species of Aphclinus into a new genns. but he never carried out his suggestion for the reason, I believe, that he was not entirely sure of the characters of the type species of the genus. Since that time Kiurdumoff has given a synopsis of the European species of Aphelimus, and has shown clearly that the genotype, A. abdominalis (Dalman) is an aphisfeeding species. It is, nevertheless, still desirable to divide Aphelinus, but now it is apparent that coccid-feeding species
are the ones to be segregated. Two generic names are available for this group of species: Prosaphclinus De Gregorio, 1915, about which there is no doubt, and Aphytis Howard, 1900, which by the original description was said to differ from Aphelinus in having one less funicle joint. Mercet has already pointed out that Aphytis chilensis Howard in all probability is closely allied to his Aphelimus longiclavac, and therefore similar also to $A$. capitis Rust. I believe it is safe to conclude that Aphytis chilensis really has three funicle joints, with the first one very small and overlooked by Dr. Howard, and I therefore adopt this name for the group of the old genus Aphelinus containing the coccid-feeding species.*

The two genera Aphelinus and Aphytis as here recognized have much in common but most of the species differ considerably in habitus. Aphelinus, at least typically, has a broad head and the body tapering behind it to the apex of the abdomen, but the essential generic difference lies in the ovipositor. This in Aphelinus is comparatively tenuous and is enclosed entirely by the ventrites so that in oviposition it is protruded backward in a more or less horizontal position. In Aphytis the head, thorax and abdomen do not differ greatly in width, and the ovipositor is comparatively strong and entirely free, so that in oviposition it descends almost perpendicularly from near the base of the abdomen.

Two Hawaiian species belong to Aphytis as here recognized, viz: Aphytis diaspidis (Howard) and A. limonus (Rust).

## Trichogr.inmatidae.

Megaphragma new genus.
Female. Head apparently very thin fronto-occipitally, the frontovertex somewhat wider than one-third of the whole head, the eyes large, the eheeks rather short, the sides of the head and the cheeks gibbously convergent on the mouth. Ocelli apparently absent. Antennae (Fig. 7a) inserted very high on the face between the eyes, apparently rather nearer

[^3]to the oceipital margin than to the month, and six jointed; scape sub-fusiform-compressed, but not very wide, ineluding the radicle about as long as the eyes; pecticel large and lyriform, contracted at apex, much thicker than the seape or the following two joints; funicle composerl of one minute ring-joint which is twice as wide as long; club as long as the rest of the antenna, three-jointed, strongly fusiform in shape, the basal joint about twice as long as wide at the base but inereasing in width toward the apex; middle joint about twice as long and thrice as wide as the precoding joint and widest just beyond the middle; apieal joint very strongly conical, nearly as long as the preceding joint, and provided with conspicuous longitudinal chitinous rilges ranning the whole length and some of them strongly projeeting at apex. Mandibles with two strong acute teeth at apex. Maxillary palpi aprarently onejointed but rather elongate and tapering; labial palpi not seen.

Nig. 7. Megaphragma mymaripenne. A. Antenna of female. B. Hind leg of female.

Thorax seareely as long as wide; pronotum not visihle from above; the parapsidal furrows strongly developet, the middle lobe of the mesosentum about as long as wide; sentellum about twice as wide as long, and very broadly rounded at apex. Abelomen broadly sessile, very slightly narrower than the thorax and slightly longer, the apex rather
narrowly rounded; phragma of the mesothorax has but slightly converging sides and it reaches almost to the apex of the abdomen; ovipositor not protruded, and internally it reaches almost to the base of the abdomen; thorax and abdomen together form an oral mass nearly twice as long as wide.

Legs (Fig. 7h) of moderate length, the femora rather stout hut compressed, the front tibiae also considerably enlarged; middle and hind tilniae and all the tarsi cylindrical and slenter, the tarsi rather long although only three-jointed.

Wings resembling a typical Mymarid wing in shale, being linear, about seven times longer than wide, and laving an exceedingly long marginal fringe; venation reaching about to the mithle of the costal margin, the submarginal and marginal veins about equal in length, the stigmal vein short and stubly, the postmarginal rein absent; costal cell extremely narrow; disk of wing on the apical half with a row of few fine, short setae; hind wing extremely narrow, yet rounded at apex.

Male. Not known.
Type of the genus: Megaphragma mymaripenne n. sp.
Megapliragma differs from all other Trichogrammatidae known to me except Hydrophylar Matheson and Crosby in having the wings linear and very long-fringed. Hydrophylar, however, has the thorax and abdomen combined about four times as long as wide, the legs considerably longer and slenderer, the antennae eight-jointed with two well-developed funicle joints besides an annellus, and with a comparatively small three-jointed club. In Girault's classification Megaploragma falls in the tribe Lathromerini but differs from all the included genera with sixjointed antennae in having the wings very narrow and longfringed.

## Megaphragma mymaripenne n. sp. Fig. 7.

Antennae as in Fig. 7a, the middle joint of the clul) with two large setae and several smaller ones, the apical joint with one molerately long seta and with at least two of the chitinons sensoria projecting at apex.

Disk of wing with about five or six very minute setae in an irregular median longitudinal row on the apical half beyond the renation; disk narrowest opposite the apical part of the marginal rein, somewhat widening proximad and about twice as wide on apical half as at the narrowest point, the apex well rounded. Marginal vein with two fime, rather short setae at its base, and on the disk near the opposite margin just proximad of the constricted part is a somewhat longer seta. Marginal fringe
legiming on the posterior margin opposite the stigmal rein aml consisting of alont twentr-six setae, the first one opposite the stigmal vein being a little smaller than the diseal seta just preceding it which is mentioned above; the following setac raphilly increasing in Jength. those at and on both sides of the afex about one-half as long as the wing itself, those on the anterior margin gradually and slightly decreasing in length basad and abruptly terminating at a point slightly more than milway between the apex of the wing and the stigmal sein; the remainder of the costal margin to the stigmal vein provided with a fringe of exceedingly minute short setae abont five in number and visible only under high magnifieation.

Hind wing execedingly marrow but triangularly widened at the hooklets, and slightly widened again at the apex which is roundel; no discal setae present; marginal fringe eomposed of twelve setae begimning on the posterior margin just beyond the hooklets and abruptly terminativg on the anterior margin at the apex of the wing, only two of the setae being situated on the anterior side of the apex; the setac also rapidly inerease in length towards the apex, where they are only slightly shorter than those of the fore-wing.

Tarsi of front legs distinetly longer than the front tibias; tarsi of middle and hind legs (Fig. ib) slightly shorter than the corresponding tibiae.

No definite surface senpture observable under high magnifieation.
Head and thorax rather pale yellow, the eyes black; antemae and legs pale yellowish; oceiput of head aml the ablemen brown; wings hyaline, but the hind pair are rather distinctly infuscated at and near the hooklets.

Length of body, 0.252 ; length of antenna, 0.162 ; length of fore-wing. 0.209 ; greatest wialth of fore-wing, 0.031 ; greatest length of marginal fringe of fore-wing, 0.135 ; width of thorax, 0.11 s ; length of thorax and abdomen eombined, 0.195 mm .

Described from two females (holotype and paratype) mounted on a slide with fragments of about three other females which were accidentally crushed during preparation. These specimens were collected by Mr. C. E. Pemberton late in Jannary, 1920, on the leaves of a forest tree at Mountain View, Hawaii, where they were associated with Thysanoptera. Mr. lemberton had a suspicion at the time that the Megaploragma were parasitic on the thrips. This species is presumably an immigrant in the Hawaiian Islands, but of this there is, of course, no direct proof at present.

## Aphelinoidea xenos n. sp. Fig. S.

Female. Structurally similar to A. semifuscipemes Girault, but the hasal joint of the club shows no transverse groove or suture on the ventral
side near the middle, the apieal margin of the joint is more nearly straight on both sides, or only gently areuate, whereas it is deeply angularly emarginate on the outer surface in semifuscipennis; the fore-wing narrower with fewer or aboat twenty discal hair lines at widest part of the disk, semifuscipennis having about twenty-five to twenty-eight lines, the disk, therefore, distinctly more sparsely pubescent; the marginal fringe distinctly longer and practically equal to one-fifth of the greatest width of the disk, but in semifuscipennis equal to about one-seventh of the width of the disk.

Fig. 8. Aphelinoided xenos. Antenna of female.

General eolor much paler than in semifuscipennis or yellowish brown instead of piceous. Dry speeimens are brown, with most of the head, the dorsum of the thorax and sometimes apex of the abdomen above paler and more or less yellowish, and with the lower half of the oceiput, the cheeks, lower part of the face, the sternum, pleura, and most of the ablomen fuscous brown. In balsam mounts the coloration is dusky yellow, with the lower half of the oceiput, the cheeks, oral margin of face, sternum, pleura, and transterse bands on the abdomen appearing rather dilutely fuscous, these darker parts being not rery eonspicuous nor sharply bounded except on the oceiput, the bands on the abdomen sometimes confined to the basal half or two-thirds; rest of the face, apex, and part of the venter of abdomen purer brighter yellow, the frontovertex orange yellow; eyes and ocelli bright carmine; antennae clear yellow; legs dusky with the tips of the tibiae and the tarsi paler and more yellowish.

Wings hyaline, but with basal part beneath the renation elouded with fuscous, the apical margin of the eloud extending slightly obliquely distan from the apex of the stigmal vein towards the opposite margin and into the pubeseent area of the disk; the elond also with a darker triangular area beneath the apex of the marginal vein, the apex of the triangle touching the vein; just proximad is a slightly elearer area, somewhat similar in shape, but smaller and with the base of the triangle against the vein, sometimes this elearer area is more diffused and extends along the rein towards the base of the wing; hind-wings with a short slightly clouded
area beneath the apieal half of the renation; marginal vein of both fore and hind-wings distinetly more infuscated than the rest of the venation.

The following measurements are given in a eolum parallel with similar measurements of semifuscipennis:

|  | xenos | semifuscipenmis |
| :---: | :---: | :---: |
| Length of body to apex of oripositor ( 0.471 | to) . 0.635 mm . | 0.537 mm . |
| Length of antema . | . 0.234 mm . | 0.294 mm . |
| Length of seape | . . 0.081 mm . | 0.079 mm . |
| Length of pedieel | .0 .049 mm . | 0.045 mm . |
| Length of club | . 0.103 mm . | 0.098 mm . |
| Length of basal club joint | .0 .037 mm . | 0.035 mm . |
| Leagth of pedicel and flagelhm | .0 .153 mm . | 0.145 mm . |
| Length of fore-wing | . 0.475 mm . | 0.499 mm . |
| Width of forewing | 0.191 mm . | 0.215 mm . |
| Length of marginal fringe of fore-wing | . 0.040 mm . | 0.037 mm . |

Male. Very similar to the female, but with the antennae slenderer, the two joints of the club praetically equal in length, the wings narrower, with the diseal pubeseence somewhat sparser and the marginal fringe distinctly longer or nearly one-third as long as the greatest width of the disk.

Coloration as in the female, except that the fuscous bands on the abdomen are confined entirely to the basal half or a little more than half ot abdomen, the fuscous eloud at base of wings somewhat paler.

Length of body, ( 0.417 to) 0.60 S ; length of antema, 0.222 ; length of scape, including radicle, 0.053 ; length of pedicel, 0.048 ; length of elub, 0.051 ; length of basal joint of elub, 0.041 ; length of pedieel and flagelhm combined, 0.138 ; length of fore-wing, 0.47 s ; greatest with of fore-wing, 0.163 ; length of marginal fringe of fore-wing, 0.051 mm .

Described from 21 females, 20 males (holotype, allotype. male and paratypes) mounted on slides and reared by Mr. Swezey from the eggs of Sogata paludum. (Kirkaldy) collected at Kewalo in Honolulu on August 18, 1913, and on May t, 1914; and 1t specimens (paratypes) of undetermined sex. mounted on cards and reared with the preceding specimens.

[^0]:    Proc. Haw. Eint. Soc., V', No. 3, December, 192.4.

[^1]:    * I have since examined the type of Zaomma artontipes, which mfortumately has been hadly mutilated, the hear leeing in fragments on a slide. Zaomma has the thorax strongly eonsex above, the axillae rather well separated and slightly chevated above the scotellum: the latter is

[^2]:    * Head somewhat shriveled, so that the measurements are necessarily more or less inatceurate.

[^3]:    * Subsequent examination of the type of Aphytis chilensis in the National Mnseum does not lead me to ehange the above statement. Only two funicle joints are actually visible in the mique type, but the antennae are so folded beneath the head that an unobstructed view of the base of the funicle ean not be oltained.
